Introduction

The main advantages of chemical processing under micro-flow conditions are well known. Mass transfer problems are commonly solved by the use of micro mixers, which allow mixing faster than the chemical reaction proceeds. Micro heat exchangers ensure e.g. safe processing of chemical reactions with high heat release, or for fast quenching of temperature-sensitive products. In addition, the application of unusual \( T, p \) process regimes are advantageous. However, the broadening of the residence time distribution in homogenous flow due to the developed Poisueille profile inside micro channels or capillaries should be taken into account. With segmented-based microfluidics, e.g. formed as single or double emulsion droplets, a well-defined and reproducible residence time distribution could be achieved. Good examples for the influence of mixing and flow regime are the selective mono-Wittig reaction on a symmetrical, bifunctional dicarbonyl compound (benzene-1,4-dicarboxaldehyde), and the phase-transfer catalysis (PTC) performed in double emulsion segments with an inert core droplet moves along the phase boundary of the shell segment and continuous phase and acts as an “internal mixer” by shaking or jiggling the reactor.

**Residence Time Distribution: Laminar Flow Tube Reactor**

Dispersion becomes dominant for laminar flow in a tube reactors with a small diameter!

**Residence Time Distribution: Segmented Flow**

For example:
- Droplet diameter: \( D = 500 \) \( \mu \)m
- Volume: \( V = 6.54 \times 10^{-11} \) \( m^3 \)
- Surface area: \( A_s = 7.85 \times 10^{-17} \) \( m^2 \)
- Specific surface area: \( A_s = 12.000 \) \( m^2 \)

**Selective Olefination: WITTIG-Reaction**

**Phase-Transfer-Catalysis (PTC): Etherification**

**Summary**

- Dispersion becomes dominant for laminar flow in tube reactors with a diameter in the \( \mu \)m or \( mm \) range! Laminar flow in tube reactors with small diameters (\( mm \) to \( \mu \)m) increases residence time distribution. Residence time is no longer valid!
- Mass transfer can be enhanced by forced mixing within segment by jiggling an internal droplet, e.g. for PTC reactions
- Selective Wittig olefination can only be realized by segmented flow conditions successfully

Solution: Performing chemical reactions in segments or droplets in continuous flow
